# CSE 3318

Week of 07/10/2023

Instructor: Donna French

#### Formatted Input and Output

```
sscanf() and sprintf()
sscanf (buffer, control string, args, ...)
sprintf(buffer, control string, args, ...)
                    buffer in memory
buffer
                    conversion specifier
control string
                    argument to conversion specifier
args
```

#### Formatted Input and Output

```
char buffer[100] = \{\};
char first name [50] = \{\};
char last name[50] = \{\};
                               Enter first name Fred
char id[10] = \{\};
char a[50] = {};
                               Enter last name Flintstone
char b[50] = \{\};
char c[10] = \{\};
                               Enter id 100000001
printf("Enter first name ");
scanf("%s", &first name);
printf("\nEnter last name ");
scanf("%s", &last name);
printf("\nEnter id ");
scanf("%s", &id);
```

```
Breakpoint 2, main () at sprintfDemo.c:23
23
          sprintf(buffer, "%s %s has student id %s ",
24
                first name, last name, id);
(qdb) p first name

$10 \ "1000000001"
```

To create an adjacency matrix, we need a list of edges.

This list could be entered at prompts or read from a file.

Using the input list, each edge could be marked with a 1 in the matrix to indicate an edge.

Once the matrix is complete, a vertex's adjacent vertices can be found.

List the edges for this undirected graph

```
int main(void)
     int AdjMatrix[MAX][MAX];
     CreateAdjacencyMatrix (AdjMatrix);
     PrintAdjacencyMatrix (AdjMatrix);
     FindAdjacentVertex(AdjMatrix);
     return 0;
```

```
void CreateAdjacencyMatrix(int AdjMatrix[][MAX])
  int start = 0, end = 0;
  int i = 0, j = 0;
  char buffer[100] = \{\};
  FILE *FH = fopen("EdgeList.txt", "r+");
  if (FH == NULL)
    exit(0);
  /* initialize adjacency matrix to 0 */
  for (i = 0; i < MAX; i++)
    for (j = 0; j < MAX; j++)
      AdjMatrix[i][j] = 0;
```

```
EdgeList.txt

0 3
1 2
2 3
2 4
4 3
```

```
/* initialize adjacency matrix to 0 */
for (i = 0; i < MAX; i++)
  for (j = 0; j < MAX; j++)
                                         Inside the function to create the matrix and can be run
                                                 anytime needed for any value.
    AdjMatrix[i][j] = 0;
VS
/* initialize adjacency matrix to 0
                                                       Can ONLY be done when the array
int AdjMatrix[MAX][MAX] = {};
                                                             is declared.
VS
                                                          Does NOT set all elements of
/* initialize adjacency matrix to -1 */
```

int AdjMatrix [MAX]  $[MAX] = \{-1\}$ ;

the array to -1.

There is another way...

```
memset(AdjMatrix, -1, MAX*MAX*sizeof(int));
```

There are a couple of things you need to understand about using this method to initialize an array.

```
memset(AdjMatrix, -1, MAX*MAX*sizeof(int));
Why use MAX*MAX*sizeof(int) instead of sizeof(AdjMatrix) or 25?
memset (AdjMatrix, -1, sizeof (AdjMatrix));
GraphAM.c: In function 'CreateAdjacencyMatrix':
GraphAM.c:47:33: warning: 'sizeof' on array function
parameter 'AdjMatrix' will return size of 'int (*)[5]'
[-Wsizeof-array-argument]
   47 | memset(AdjMatrix, -1, sizeof(AdjMatrix));
```

```
memset(AdjMatrix, -1, sizeof(AdjMatrix));

GraphAM.c: In function 'CreateAdjacencyMatrix':

GraphAM.c:47:33: warning: 'sizeof' on array function parameter 'AdjMatrix' will return size of 'int (*)[5]' [-Wsizeof-array-argument]

47 | memset(AdjMatrix, -1, sizeof(AdjMatrix));
```

But it's just a WARNING and warnings don't matter - right???

Since we still got an executable, let's run it and see if JUST a warning matters.....

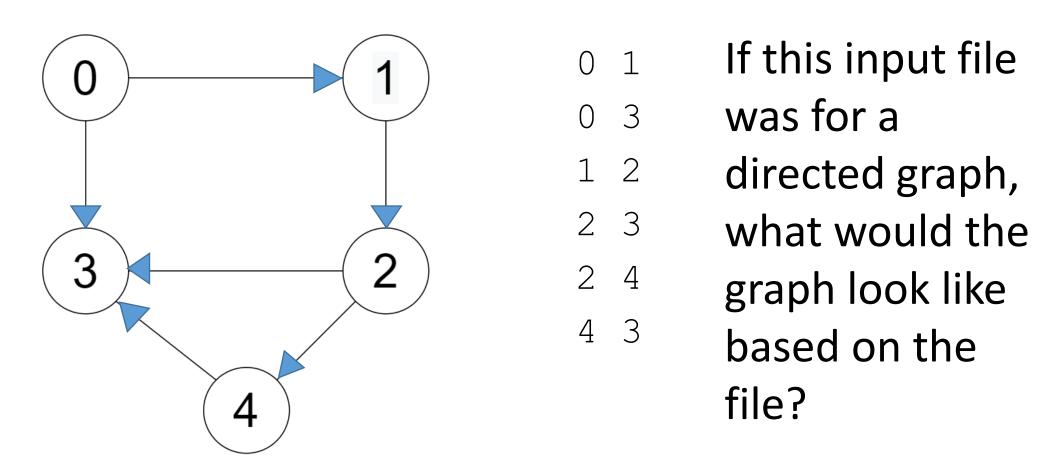

```
48
      memset (AdjMatrix, -1, sizeof (AdjMatrix));
(qdb) p AdjMatrix
$1 = (int (*)[5]) 0x7ffffffe230
                        (gdb) p sizeof(AdjMatrix)
$4 = 8
(gdb) p *AdjMatrix
$2 = \{-1, -1, 0, 0, 0\}
(gdb) p *AdjMatrix@5
\{0, 0, 0, 0, 0\}, \{0, 0, 0, 0, 0\}\}
```

```
memset (AdjMatrix, -1, 25); //25 is MAX*MAX
48
(qdb) p *AdjMatrix@5
$1 = \{\{-1, -1, -1, -1, -1\}, \{-1, 255, 0, 0, 0\}, \{0, 0, 0\}\}
0, 0, \{0, 0, 0, 0, 0\}, \{0, 0, 0, 0, 0\}
(qdb) p/x *AdjMatrix@5
$2 = {{0xfffffff, 0xfffffff, 0xffffffff, 0xffffffff,
Oxffffffff, 0xff, 0x0, 0x0, 0x0, (0x0, 0x0,
0x0, 0x0, 0x0\}
```

```
memset (AdjMatrix, -1, MAX*MAX*sizeof(int));
 48
    (qdb) p *AdjMatrix@5
 $1 = \{\{-1, -1, -1, -1, -1\}, \{-1, -1, -1, -1, -1\}, \{-1, -1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\}, \{-1, -1\},

A graph is collection of two sets, *V* and *E*, where V is a finite non-empty set of vertices and E is a finite non-empty set of edges.

Vertices can also be called the nodes in the graph.

Two adjacent vertices are joined by edges.

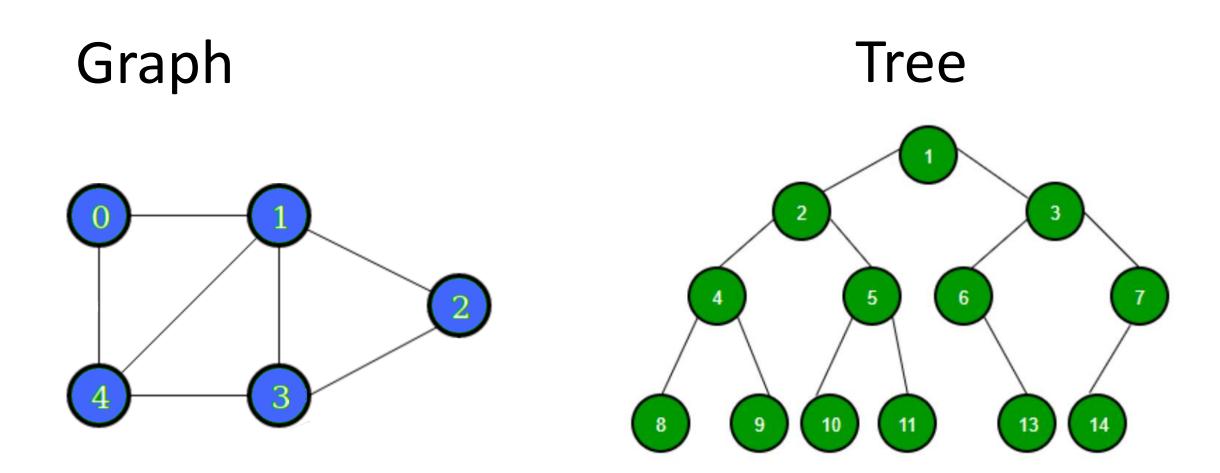

A graph is denoted as  $G = \{V, E\}$ .

A tree is a finite set of one or more nodes such that –

There is a specially designated node called root.

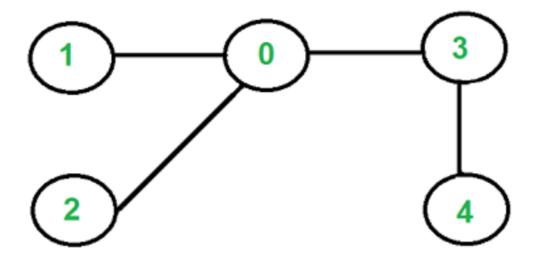

The remaining nodes are partitioned into  $n \ge 0$  disjoint sets  $T_1$ ,  $T_2$ ,  $T_3$ , ...,  $T_n$ 

where  $T_1$ ,  $T_2$ ,  $T_3$ , ...,  $T_n$  are called the subtrees of the root.

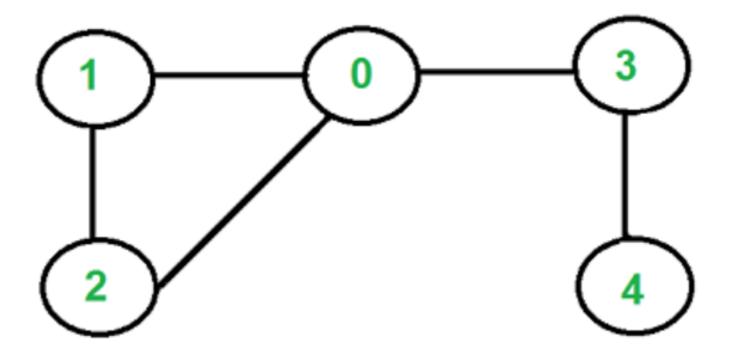

Graph	Tree

Graph or tree or both?

Graph or tree or both?

Trees are a special case of graph.

Trees are minimally connected graph.

Every tree can be considered a graph, but every graph cannot be considered a tree.

Cycles are not allowed in trees but are allowed in graphs.

If you can get from vertex A to vertex B by traveling over a sequence of edges, then we say that there is a **path** between them.

If there is a **path** between every pair of vertices, then we say the graph is **connected**. This does not mean that every vertex has an edge connecting it to every other vertex.

A connected graph with no cycles is called a **tree**. A tree is a minimally connected graph.

A **cycle** is a path with no repeated edges that repeats a vertex more than once.

In a **free** tree, no vertex/node is specified as the root.

In a rooted tree, you pick a vertex as a root and let all the other vertices hang below it.

# **Graph Traversal**

The process of visiting and exploring a graph for processing is called graph traversal.

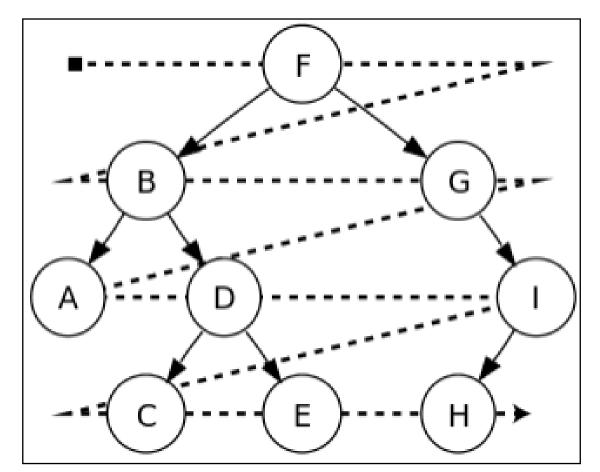

To be more specific it is all about visiting and exploring each vertex and edge in a graph such that all the vertices are explored exactly once.

There are several graph traversal techniques such as Breadth-First Search and Depth First Search.

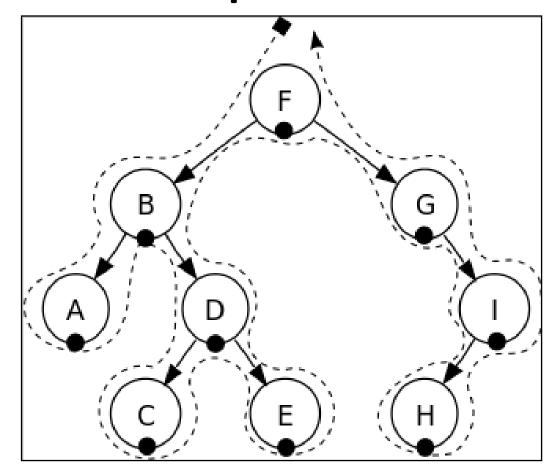

The challenge is to use a graph traversal technique that is most suitable for solving a particular problem.

# Breadth-first vs Depth-first Traversal

#### **Breadth-first**

#### **Depth-first**

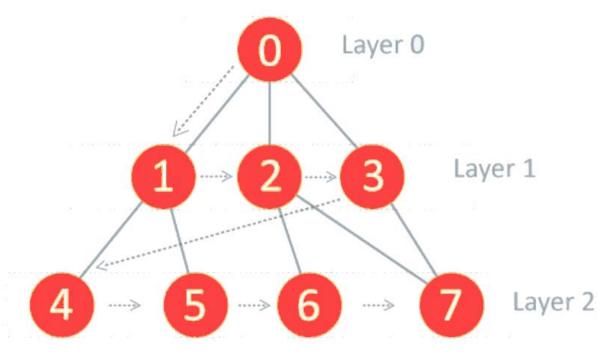

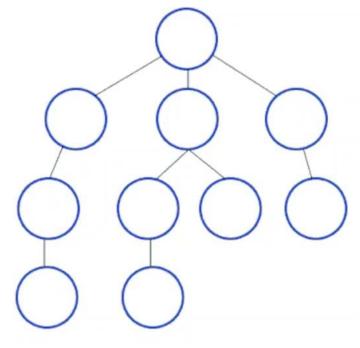

# Depth-first Traversals

- Inorder Traversal
  - Gives us the nodes in increasing order
- Preorder Traversal
  - Parent nodes are visited before any of its child nodes
  - Used to create a copy of the tree
  - File systems use it to track your movement through directories
- Postorder Traversal
  - Used to delete the tree
  - File systems use it to delete folders and the files under them

#### Breadth-first Search

Breadth-First Search algorithm is a graph traversing technique, where you select a random initial vertex and start traversing the graph layerwise in such a way that all the vertices and their respective adjacent vertices are visited and explored.

#### Breadth-first Search

Breadth-first Search can find the shortest path from a source vertex to any other vertex in a graph.

Shortest, in this context, means the least number of edges.

We are going to start with undirected graphs.

A queue is an abstract data structure that follows the

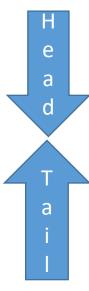

First-In-First-Out (FIFO)

methodology.

Data inserted first (FI) will be accessed first (FO).

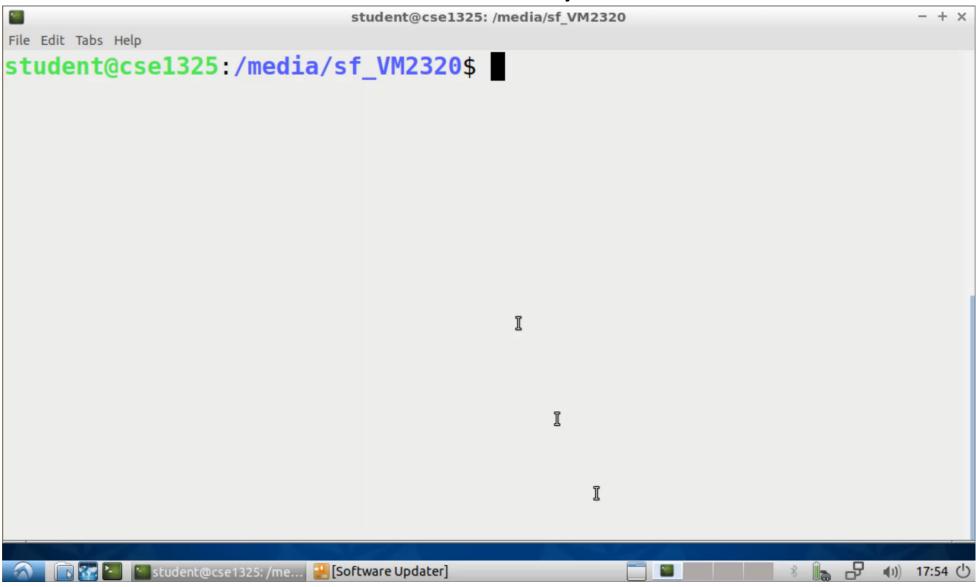

Data is added (enqueue) at one end (tail)

Data is removed (dequeue) at the other end (head).

```
65 int main (void)
66
67
        int QueueArray[MAX];
68
        int tail = -1;
        int head = -1;
```

```
enqueue(QueueArray, &head, &tail);
dequeue(QueueArray, &head, &tail);
```

```
12 void enqueue (int QueueArray[], int *head, int *tail)
13 ₽{
14
        int enitem = 0;
15
16
        if (*head > *tail)
17
18
            *head = -1;
            *tail = -1;
19
20
21
22
        if (*tail == MAX - 1)
23
            printf("Queue Overflow \n");
24
        else
25
26
            if (*head == -1) /*If queue is initially empty */
27
                *head = 0;
28
            printf("\nEnter element to enqueue : ");
29
            scanf("%d", &enitem);
30
            (*tail)++;
31
            QueueArray[*tail] = enitem;
32
            display(QueueArray, *head, *tail);
33
34 1
```

```
12 void enqueue (int QueueArray[], int *head, int *tail)
13 ₽{
14
       int enitem = 0;
15
16
       if (*head > *tail)
17
18
            *head = -1;
19
            *tail = -1;
20
```

```
22
        if (*tail == MAX - 1)
23
            printf("Queue Overflow \n");
24
       else
25
26
            if (*head == -1) /*If queue is initially empty */
27
                *head = 0;
28
            printf("\nEnter element to enqueue : ");
29
            scanf("%d", &enitem);
30
            (*tail)++;
31
            QueueArray[*tail] = enitem;
32
            display(QueueArray, *head, *tail);
33
```

```
void dequeue(int QueueArray[], int *head, int *tail)
37 ₽{
38
        if (*head == -1 \mid \mid \mid *head > *tail)
39
40
            printf("\n\nQueue is empty\n\n");
41
42
        else
43
44
            printf("\n\nDequeue %d\n", QueueArray[*head]);
45
             (*head)++;
46
            display(QueueArray, *head, *tail);
```

```
void display(int QueueArray[], int head, int tail)
51 ₽{
52
        int i = 0;
53
54
        if (head == -1)
55
            printf("\n\nQueue is empty\n\n");
56
        else
57
58
            printf("\n\nQueue : ");
59
            for (i = head; i <= tail; i++)</pre>
                printf("%d ", QueueArray[i]);
60
61
            printf("\n\n");
62
63
```

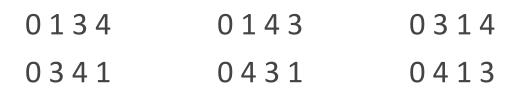

Vertex 0 is the starting vertex.

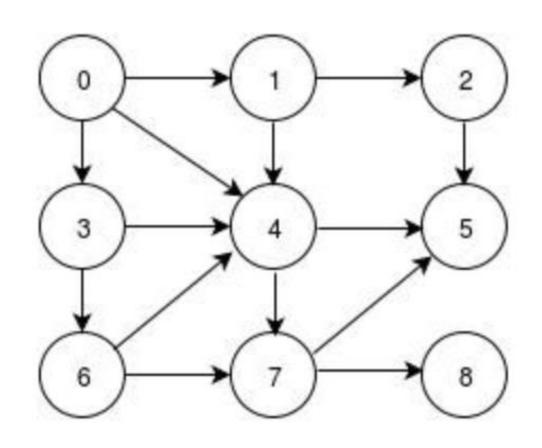

We will visit all vertices adjacent to vertex 0

1, 4, 3

We can visit these three vertices in any order.

A traversal could be any of these combinations:

We mark 0, 1, 4 and 3 as "visited".

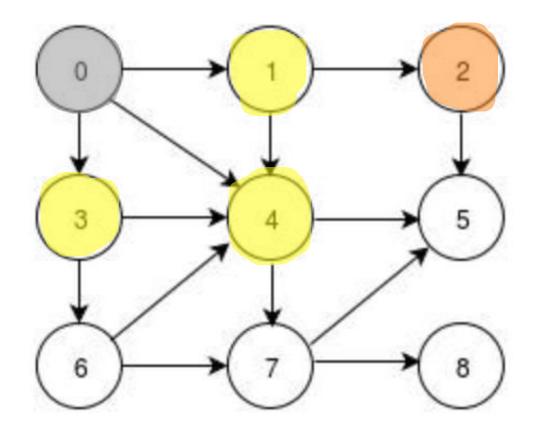

Now we visit all the vertices adjacent to 1

2, 4 but 4 has already been visited so we skip it

Our traversal is now any of these combinations :

01342 01432 03142

03412 04312 04132

Using traversal

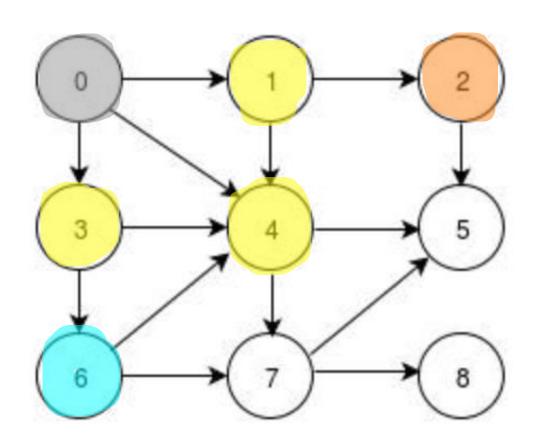

we will visit all the vertices adjacent to 3

6, 4 but 4 has already been visited so we skip it

Now our traversal is

Using traversal

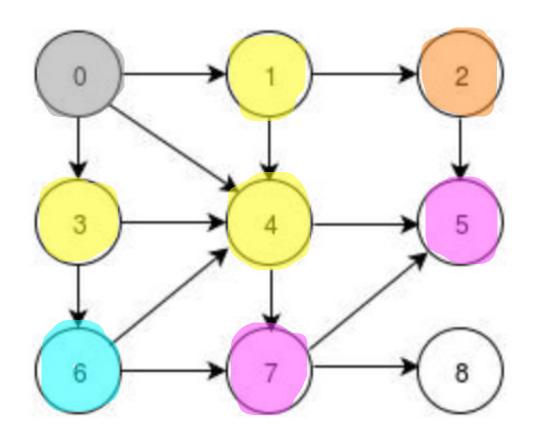

we will visit all the vertices adjacent to 4

5, 7

Now our traversal is

Using traversal

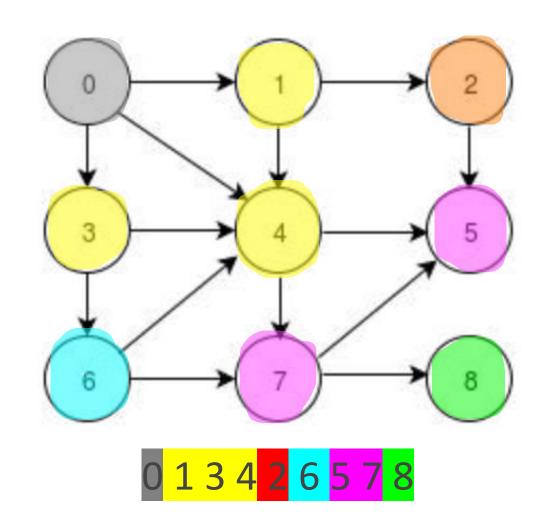

we will visit all the vertices adjacent to 2 5 but 5 has already been visited

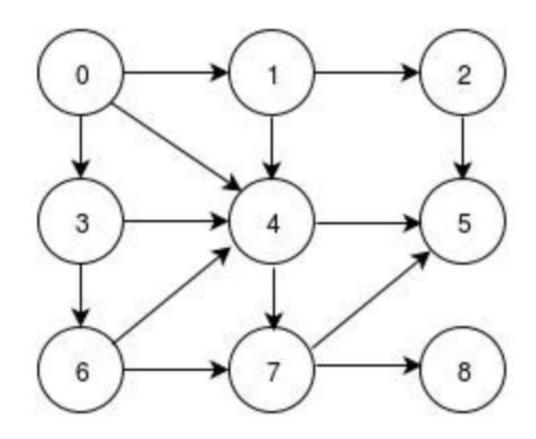

Now we visit all vertices adjacent to 6 4, 7 – both have already been visited

Now we visit all vertices adjacent to 5 There are none.

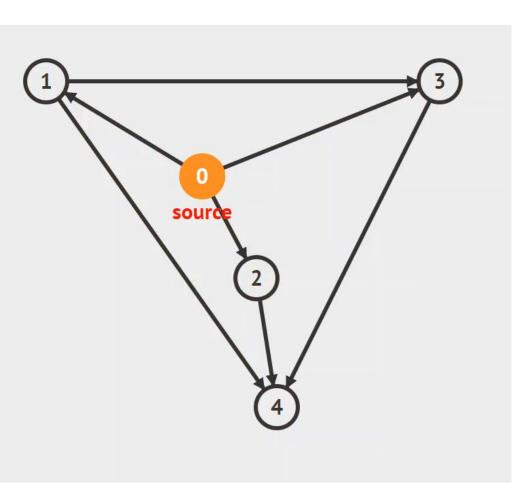

Now we visit all vertices adjacent to 7 8 has not been visited so we add it to our traversal

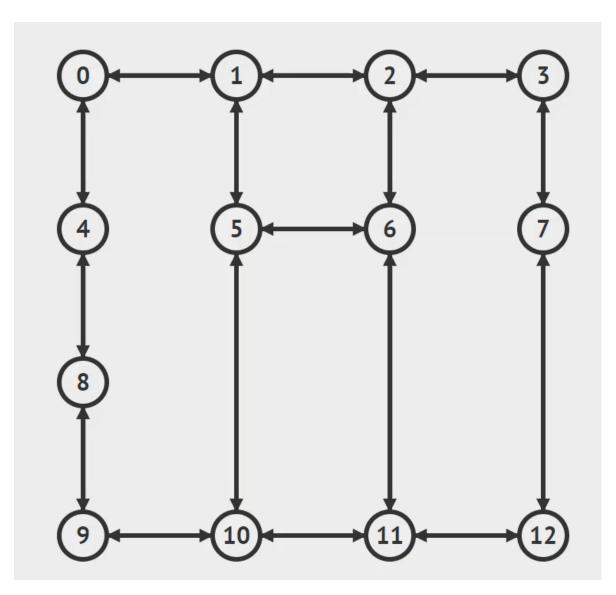

There's no unique traversal and it can be different based on the order of the successors.

#### **Crawlers in Search Engines**

Breadth-First Search is one of the main algorithms used for indexing web pages.

The algorithm starts traversing from the source page and follows all the links associated with the page.

Each web page is a node in a graph.

#### **GPS Navigation systems**

Breadth-First Search is one of the best algorithms used to find neighboring locations by using the GPS.

#### Find the Shortest Path for an unweighted graph:

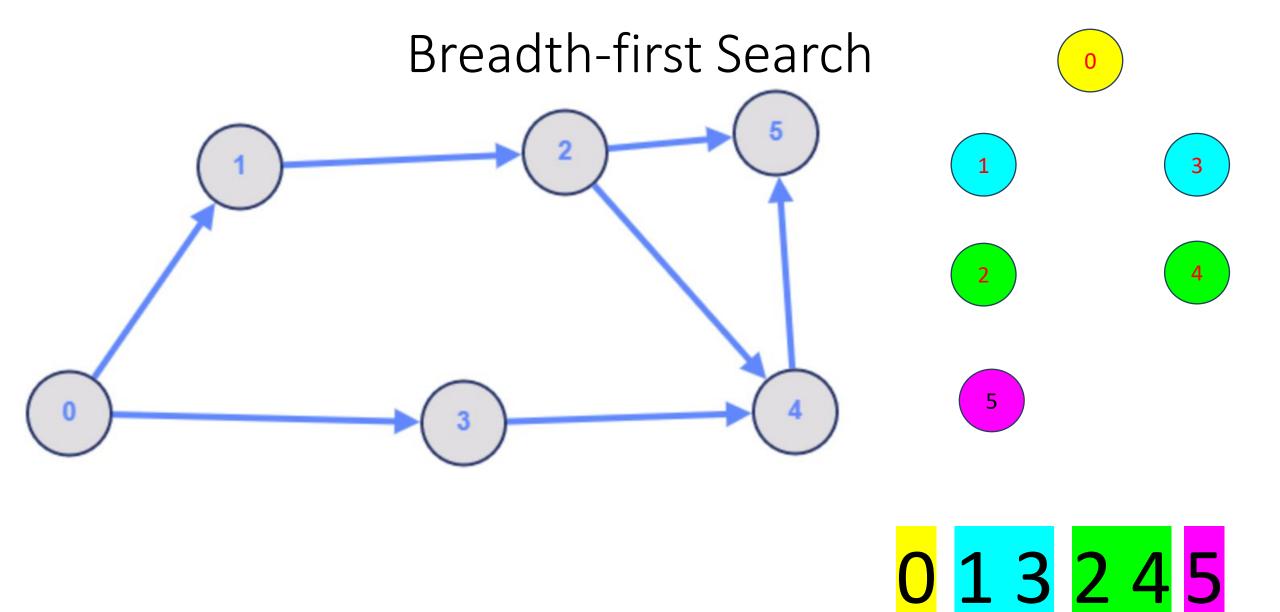

When it comes to an unweighted graph, calculating the shortest path is quite simple since the idea behind the shortest path is to choose a path with the least number of edges. Breadth-First Search can allow this by traversing a minimum number of nodes starting from the source node.

#### **Broadcasting**

Networking makes use of what we call as packets for communication. These packets follow a traversal method to reach various networking nodes. One of the most commonly used traversal methods is Breadth-First Search. It is being used as an algorithm that is used to communicate broadcasted packets across all the nodes in a network.

#### **Peer to Peer Networking**

Breadth-First Search can be used as a traversal method to find all the neighboring nodes in a Peer to Peer Network. For example, BitTorrent uses Breadth-First Search for peer to peer communication.

We need a structure to hold our vertex information. So far, we have known a vertex by a name or label and we need to know if we have visited it.

```
typedef struct
{
    char label;
    int visited;
}
Vertex;

0 means we have NOT visited
1 means we have visited
```

We need two pieces of information to do our BFS

1. We need to be able to determine neighbors

Adjacency Matrix

2. We need to keep track of which vertices have been visited

Array that can hold vertices

#### **Adjacency Matrix**

```
int AdjMatrix[MAX][MAX];
```

#### Array to hold vertices

```
Vertex *VertexArray[MAX];
```

Note that this is an array of **pointers** to Vertex. We will be dynamically allocating each vertex as we need it and storing the pointer to its memory in the array.

We need to initialize the Adjacency Matrix first.

All elements of the 2D array need to be set to 0 to indicate that edges are not neighbors.

```
for(i = 0; i < MAX; i++)
{
    for(j = 0; j < MAX; j++)
    {
        AdjMatrix[i][j] = 0;
    }
}</pre>
```

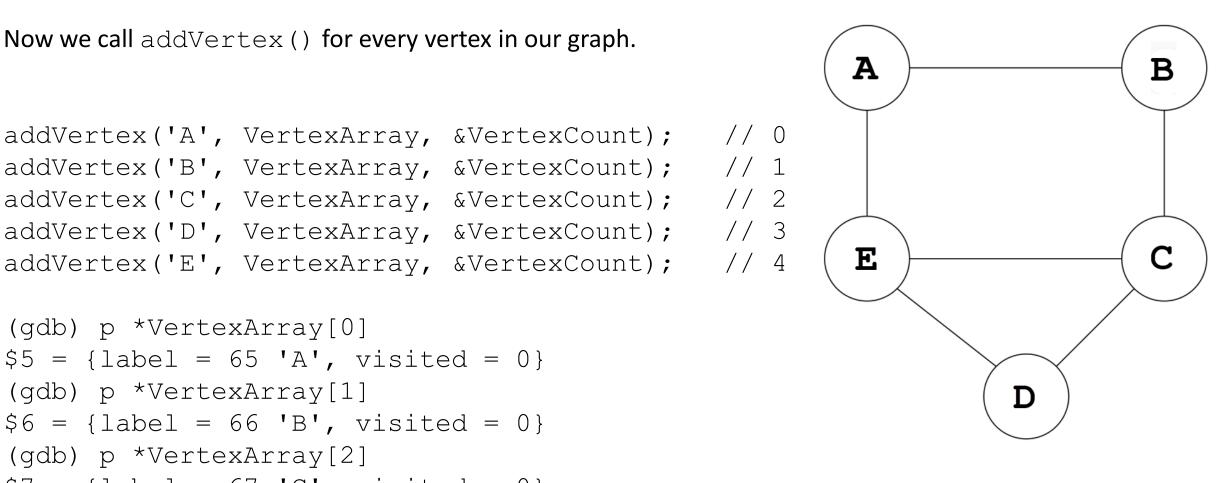

Now we need to add the vertices to the VertexArray

```
addVertex('A', VertexArray, &VertexCount);
void addVertex(char label, Vertex *VertexArray[], int *VertexCount)
     Vertex *NewVertex = malloc(sizeof(Vertex));
     NewVertex->label = label;
     NewVertex->visited = 0;
     VertexArray[(*VertexCount)++] = NewVertex;
```

Now we call addVertex () for every vertex in our graph.

addVertex('A', VertexArray, &VertexCount);

```
addVertex('C', VertexArray, &VertexCount); // 2
addVertex('D', VertexArray, &VertexCount); // 3
addVertex('E', VertexArray, &VertexCount);
(qdb) p *VertexArray[0]
$5 = {label = 65 'A', visited = 0}
(qdb) p *VertexArray[1]
$6 = {label = 66 'B', visited = 0}
(qdb) p *VertexArray[2]
$7 = {label = 67 'C', visited = 0}
(qdb) p *VertexArray[3]
$8 = {label = 68 'D', visited = 0}
(qdb) p *VertexArray[4]
$9 = {label = 69 'E', visited = 0}
```

	0	1	2	3	4
Label	Α	В	С	D	E
Visited	0	0	0	0	0

Remember that VertexArray is an array of pointers to structs of type Vertex.

	0	1	2	3	4
Label	Α	В	С	D	E
Visited	0	0	0	0	0

0	1	2	3	4
0x777ffabcd	0x777ff2bcd	0x777ffab3d	0x777ffabc4	0x777ffaecd
0x777ffabcd	0x777ff2bcd	0x777ffab3d	0x777ffabc4	0x777ffaecd
char label 'A' int visited 0	char label 'B' int visited 0	char label 'C' int visited 0	<pre>char label 'D' int visited 0</pre>	char label 'E' int visited 0

Now we need to add edges to the Adjacency Matrix.

```
addEdge(0, 1, AdjMatrix);
void addEdge(int start, int end, int AdjMatrix[][MAX])
    AdjMatrix[start][end] = 1;
    #ifdef UNDIRECTED
    AdjMatrix[end][start] = 1;
    #endif
```

Now we call addEdge () for every edge in our graph.

This is an undirected graph so we would compile our program as

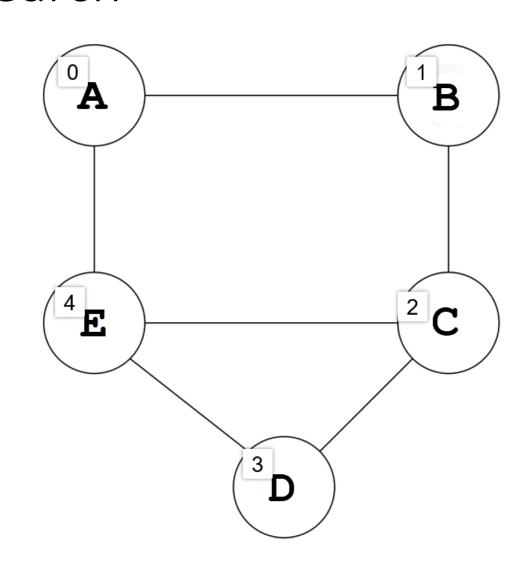

```
qcc BFSG.c -D UNDIRECTED
```

#### so that this code

```
AdjMatrix[start][end] = 1;
#ifdef UNDIRECTED
AdjMatrix[end][start] = 1;
#endif
```

#### would look like this

```
AdjMatrix[start][end] = 1;
AdjMatrix[end][start] = 1;
```

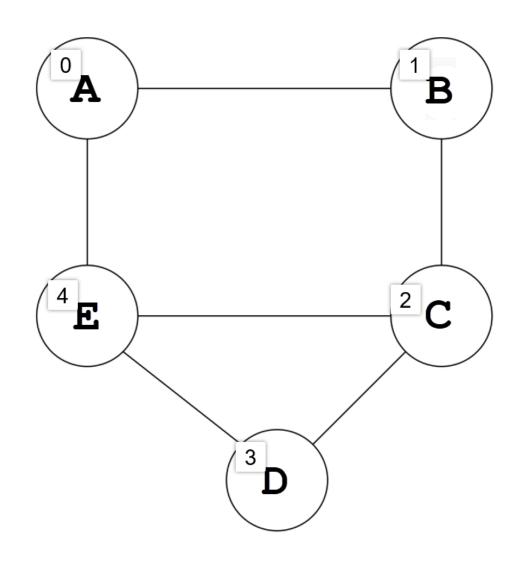

to the compiler.

Now we call addEdge () for every edge in our graph.

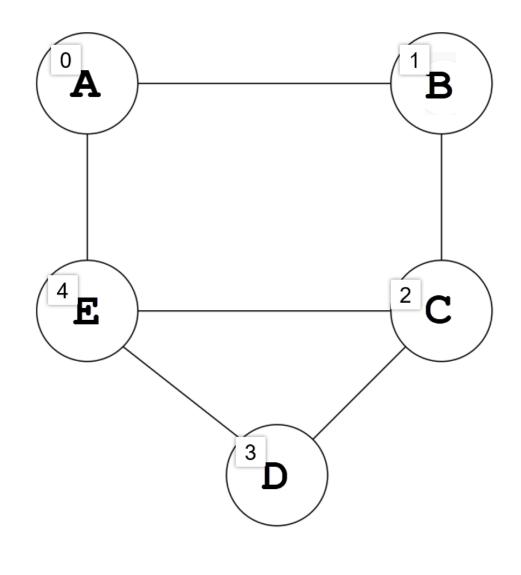

What are the edges in this graph based on the array indices assigned to each vertex?

```
0,1
1,2
2,4
4,0
1,0 or 2,1 or 4,2 or 0,4 or 3,2 or 4,3
2,3
3,4
```

```
addEdge(0, 1, AdjMatrix);
addEdge(1, 2, AdjMatrix);
addEdge(2, 4, AdjMatrix);
addEdge(4, 0, AdjMatrix);
addEdge(2, 3, AdjMatrix);
addEdge(3, 4, AdjMatrix);
```

```
addEdge(0, 1, AdjMatrix);
addEdge(1, 2, AdjMatrix);
addEdge(2, 4, AdjMatrix);
addEdge(4, 0, AdjMatrix);
addEdge(2, 3, AdjMatrix);
addEdge(3, 4, AdjMatrix);
```

We have our vertex array and adjacency matrix set up. Now we can call the Breadth First Search function.

```
BreadthFirstSearch (VertexArray, VertexCount, AdjMatrix);
```

We need to create a few items now...

```
int queue[MAX] = {};
overhead
int head = -1;
int tail = -1;
int queueItemCount = 0;
int CurrentVertexIndex = 0;
```

We are using an array for our queue. It is fast (less overhead from adding and deleting vertices) and is sufficient for what we are doing.

Our traversal will start at Vertex A

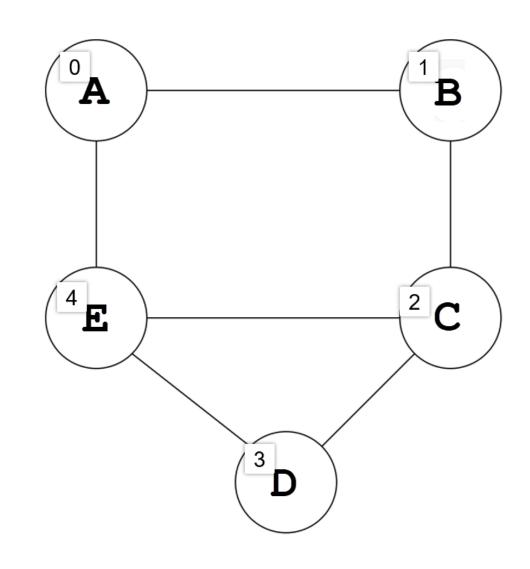

Why?

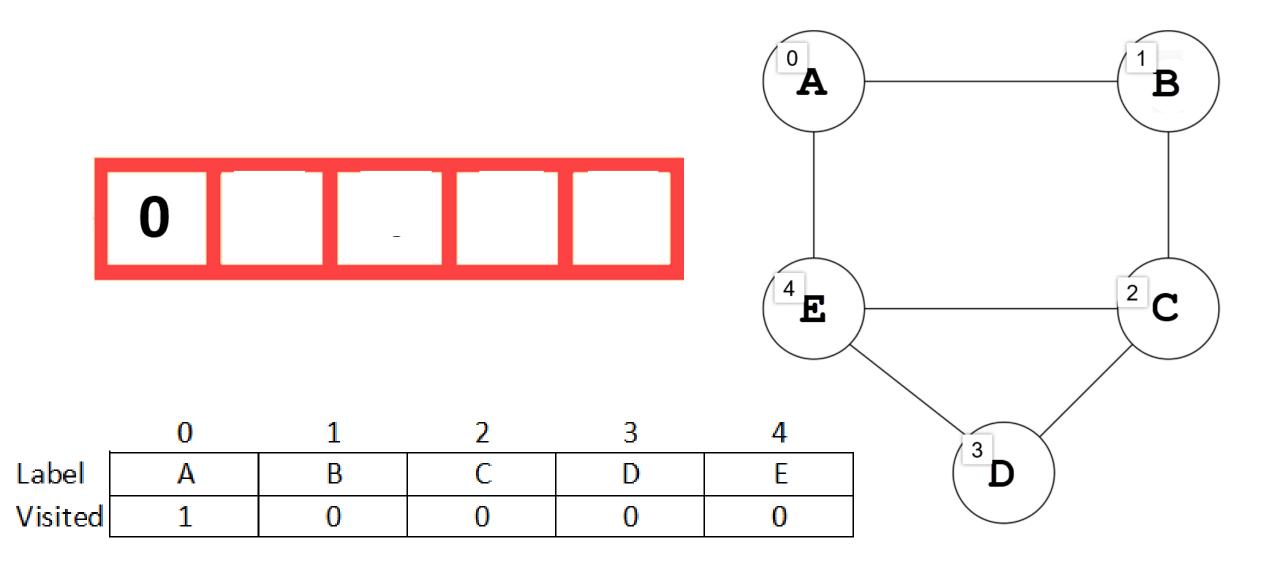

Because we said so...

When we set up the adjacency matrix and the vertex array, we decided to put Vertex A at index 0 and we are starting with index 0.

The starting vertex could be altered as needed.

Starting at index 0 is not REQUIRED.

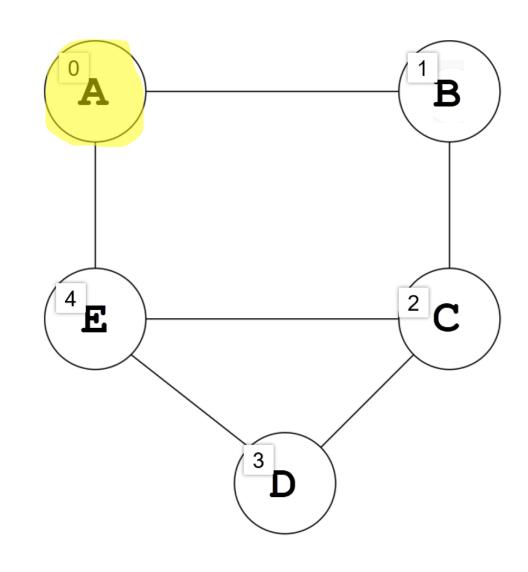

#### Our traversal will start at Vertex A

VertexArray[0]->visited = 1;

	0	1	2	3	4
Label	Α	В	С	D	E
Visited	1	0	0	0	0

Remember that VertexArray is an array of pointers to structs of type Vertex.

We are marking our starting vertex as having been visited.

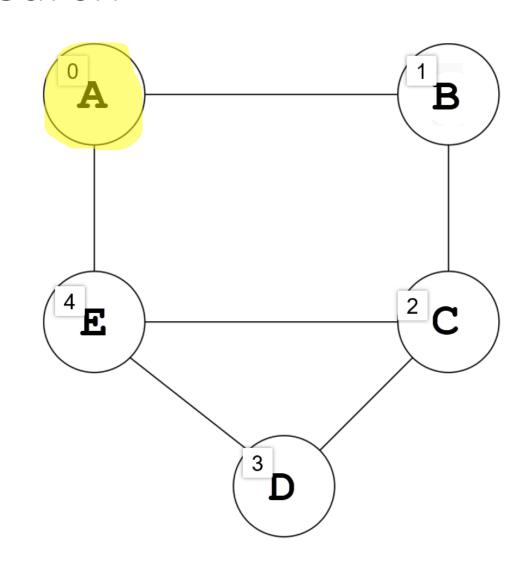

Now that we have visited Vertex A, we add it to our queue.

```
enqueue(queue, &head, &tail, 0);
queueItemCount++;
```

head and tail are both -1 (they were initialized to -1) and we are putting Vertex A's index of 0 into our queue.

We increment queueItemCount to track how many items are active in our queue.

```
37 void enqueue (int QueueArray[], int *head, int *tail, int value)
38 ₽{
39
40
       if (*tail == MAX - 1)
41
            printf("Queue Overflow \n");
42
       else
43
44
            if (*head == -1) /*If queue is initially empty */
45
                *head = 0;
46
            (*tail)++;
47
            QueueArray[*tail] = value;
48
```

```
if (*tail == MAX - 1)
   printf("Queue Overflow \n");
else
                            a
   if (*head == -1)
      *head = 0;
   (*tail)++;
   QueueArray[*tail] = value;
```

```
95
         while (queueItemCount)
 96
 97
             CurrentVertexIndex = dequeue(queue, &head, &tail);
 98
 99
             queueItemCount--;
100
101
             for (i = 0; i < VertexCount; i++)
102
103
                 if (AdjMatrix[CurrentVertexIndex][i] == 1)
104
105
                     if (VertexArray[i]->visited == 0)
106
                          enqueue (queue, &head, &tail, i);
107
108
                         queueItemCount++;
                         VertexArray[i]->visited = 1;
109
110
111
112
113
```

```
while (queueItemCount)
     CurrentVertexIndex = dequeue(queue, &head, &tail);
     queueItemCount--;
While there are unused items in the queue,
dequeue the head and place that value in
CurrentVertexIndex and decrement the
```

This is the vertex we will use to check for adjacent/neighbor vertices.

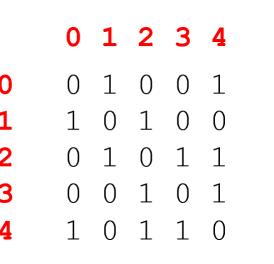

number of items in the queue.

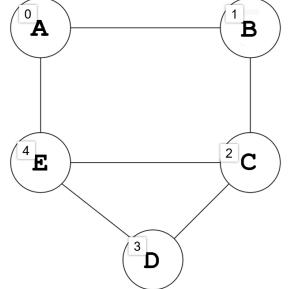

```
int dequeue(int QueueArray[], int *head, int *tail)
   int IndexAtHead = 0;
   if (*head == -1 \mid \mid *head > *tail)
      printf("\n\nQueue is empty\n\n");
      IndexAtHead = -1;
   else
      IndexAtHead = QueueArray[*head];
      (*head)++;
```

return IndexAtHead;

```
for (i = 0; i < VertexCount; i++)
  if (AdjMatrix[CurrentVertexIndex][i] == 1)
    if (VertexArray[i]->visited == 0)
       enqueue (queue, &head, &tail, i);
       queueItemCount++;
       VertexArray[i] -> visited = 1;
```

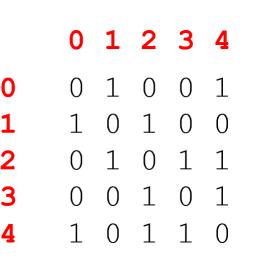

```
for (i = 0; i < VertexCount; i++)
    if (AdjMatrix[CurrentVertexIndex][i] == 1)
       if (VertexArray[i]->visited == 0)
           enqueue (queue, &head, &tail, i);
           queueItemCount++;
           VertexArray[i]->visited = 1;
```

	0	1	2	3	4
Label	Α	В	С	D	E
Visited	1	0	0	0	0

```
for (i = 0; i < VertexCount; i++)
    if (AdjMatrix[CurrentVertexIndex][i] == 1)
       if (VertexArray[i]->visited == 0)
           enqueue (queue, &head, &tail, i);
           queueItemCount++;
           VertexArray[i]->visited = 1;
```

	0	1	2	3	4
Label	Α	В	С	D	E
Visited	1	1	0	0	0

```
while (queueItemCount)
     CurrentVertexIndex = dequeue(queue, &head, &tail);
     queueItemCount--;
While there are unused items in the queue,
dequeue the head and place that value in
CurrentVertexIndex and decrement the
number of items in the queue.
```

We are now going to check for neighbors of the vertex at index 1 (Vertex B).

```
for (i = 0; i < VertexCount; i++)
    if (AdjMatrix[CurrentVertexIndex][i] == 1)
       if (VertexArray[i]->visited == 0)
           enqueue (queue, &head, &tail, i);
           queueItemCount++;
           VertexArray[i]->visited = 1;
                       a
```

	0	1	2	3	4
Label	Α	В	С	D	E
Visited	1	1	0	0	1

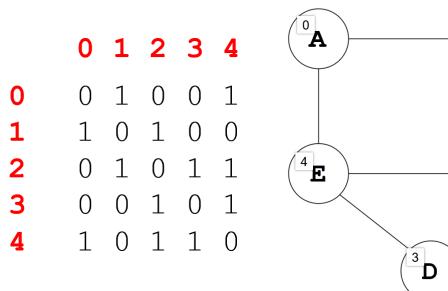

```
while(queueItemCount)
{
    CurrentVertexIndex = dequeue(queue, &head, &tail);
    queueItemCount--;
}
```

While there are unused items in the queue, dequeue the head and place that value in CurrentVertexIndex and decrement the number of items in the queue.

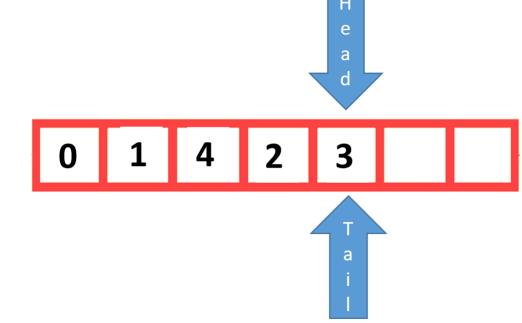

We are now going to check for neighbors of the vertex at index 4 (Vertex E).

```
for (i = 0; i < VertexCount; i++)
    if (AdjMatrix[CurrentVertexIndex][i] == 1)
       if (VertexArray[i]->visited == 0)
           enqueue (queue, &head, &tail, i);
           queueItemCount++;
           VertexArray[i]->visited = 1;
                              a
```

	0	1	2	3	4
Label	Α	В	С	D	E
Visited	1	1	1	0	1

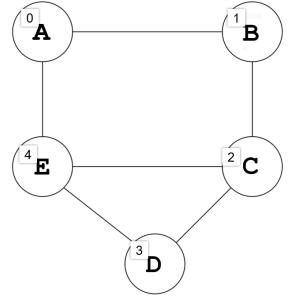

While there are unused items in the queue, dequeue the head and place that value in CurrentVertexIndex and decrement the number of items in the queue.

We are now going to check for neighbors of the vertex at index 2 (Vertex C).

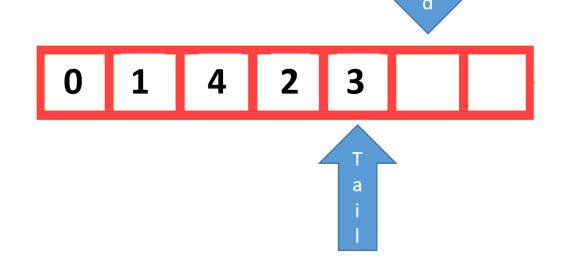

```
for (i = 0; i < VertexCount; i++)
    if (AdjMatrix[CurrentVertexIndex][i] == 1)
       if (VertexArray[i]->visited == 0)
           enqueue (queue, &head, &tail, i);
           queueItemCount++;
           VertexArray[i]->visited = 1;
```

	0	1	2	3	4
Label	Α	В	С	D	E
Visited	1	1	1	1	1

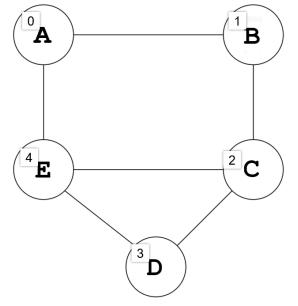

While there are unused items in the queue, dequeue the head and place that value in CurrentVertexIndex and decrement the number of items in the queue.

We are now going to check for neighbors of the vertex at index 3 (Vertex D).

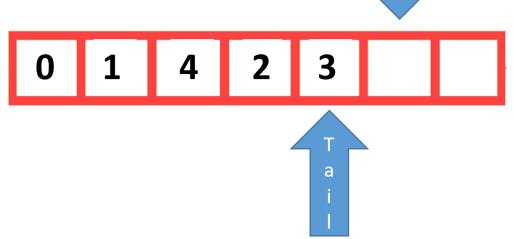

```
for (i = 0; i < VertexCount; i++)
    if (AdjMatrix[CurrentVertexIndex][i] == 1)
       if (VertexArray[i]->visited == 0)
           enqueue (queue, &head, &tail, i);
           queueItemCount++;
           VertexArray[i]->visited = 1;
```

	0	1	2	3	4
Label	Α	В	С	D	E
Visited	1	1	1	1	1

queueItemCount is now 0. The while loop will stop and the program will end.

We have traversed every vertex.

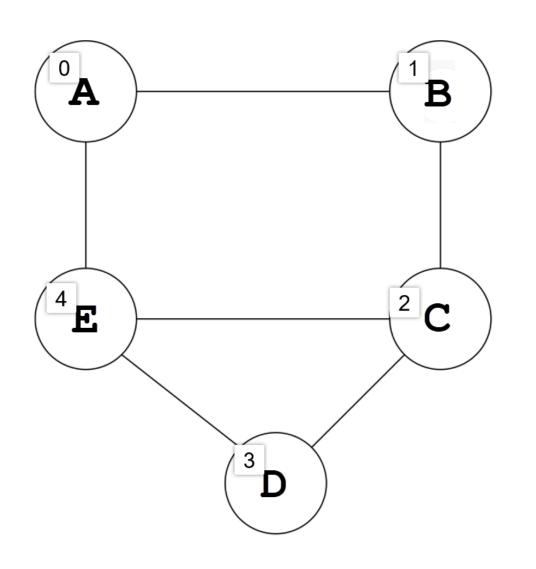

How long does breadth-first search take for a graph with vertex set *V* and edge set *E*?

It depends.....

Depends on what???

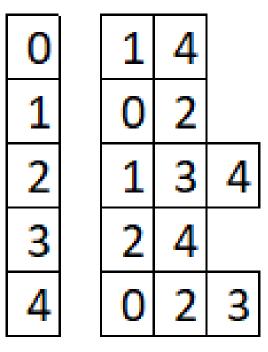

What data structure did the code use for figuring out neighbors...

	0	1	2	3	4
0	0	1	0	0	1
1	1	0	1	0	0
2	0	1	0	1	1
3	0	0	1	0	1
4	1	0	1	1	0

How many edges are in this graph?

6 or 12

0 1 2 3 4

BFS using an adjacency matrix

0 0 1 0 0

**1** 1 0 1 0

2 0 1 0 1 1

3 0 0 1 0 1

4 1 0 1 1 0

Every vertex is visited once.

To find a vertex's edges, we have to look at the entire row which has a width of V

 $O(V^2)$ 

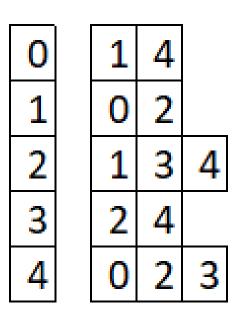

BFS using an adjacency list

Every vertex is visited once.

When a vertex is visited, we process every edge incident on that vertex

So we visit every vertex once and every directed edge once.

O(V+E)

How many vertices?

How many edges?

The BFS algorithm is particularly useful for one thing – finding the shortest path on unweighted graphs.

BFS can find the shortest path for an unweighted graph.

We will use a different algorithm to find the shortest path on a weighted graph.

Shortest does not mean unique – there can be multiple shortest paths.

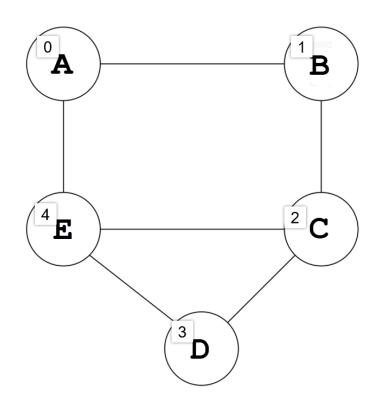

Shortest does not mean unique – there can be multiple shortest paths.

Which shortest path will be chosen will depend on the order of the vertices and how they are processed during the BFS.

Since all edges are equal in an unweighted graph, all shortest paths are valid but only one will be chosen by the code.

The first step is to add more information to our vertex structure.

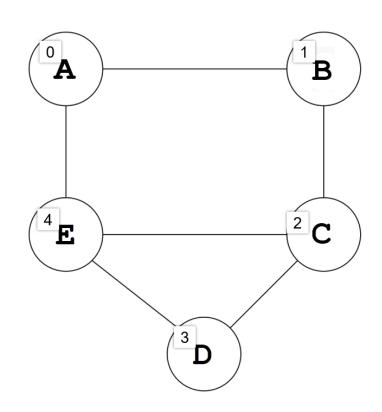

```
typedef struct
{
    char label;
    int distance;
    int previous;
    int visited;
}
Vertex;
```

When doing a BFS, we pick one vertex to be our starting point. That vertex is the vertex we put into the vertex array at cell 0.

The new distance attribute in our vertex is recording how away from the starting vertex that vertex is.

Vertex B is 1 away from Vertex A (our starting vertex) so distance in Vertex B would be set to 1.

So how would we fill in distance in the Vertex Array?

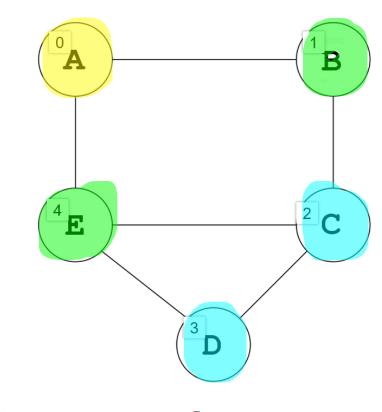

We initialize distance to -1 to show a distance has either not been calculated or that there is no edge connecting that vertex to the starting vertex.

0	<b>A</b>	<b>B</b>
(4)	<b>E</b>	2 <b>C</b>
	$\frac{3}{\mathbf{D}}$	
	4	
	E	

	U	1	2	3	4
Label	Α	В	С	D	E
Visited	0	0	0	0	0
Distance	-1	-1	-1	-1	-1

Notice that the distance source/starting vertex corresponds to the levels we create when doing a BFS.

of each vertex from the Breadth-first Search  $E^4$ 

 $D^3$ 

_	U	1	2	3	4
Label	Α	В	С	D	E
Visited	0	0	0	0	0
Distance					

Now we want to fill in our other new attribute, previous.

The previous member of the Vertex struct contains the index of the vertex we just passed through on our way to the current vertex.

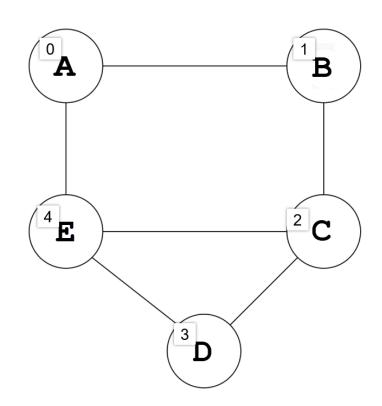

For example, to get to vertex B, we started at vertex A so we would put vertex A's index value into vertex B's previous.

So how would we fill in previous in the Vertex Array?

We initialize previous to -1 to show that this attribute has not been set or that the vertex is not connected to another vertex.

	0	1	2	3	4
Label	Α	В	С	D	E
Visited	0	0	0	0	0
Distance	0	1	2	2	1
Previous	-1	-1	-1	-1	-1

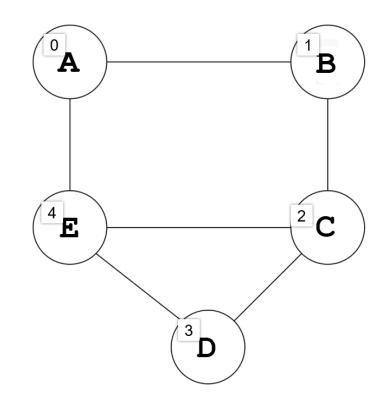

As we do our BFS, we will fill in previous.

We start with A.

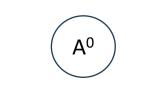

From A, we go to B and E.

We would set previous in B and E to A.

	0	1	2	3	4
Label	Α	В	С	D	E
Visited	0	0	0	0	0
Distance	0	1	2	2	1
Previous	-1	-1	-1	-1	-1

## Breadth-first Search

Using the Breadth-first Search technique to traverse a graph can give us the shortest path between two vertices when we keep track of the distance from the source vertex to every vertex and each vertex's previous vertex.

This shortest path is not unique, but it is the shortest.

This technique only works for unweighted graphs.
